Our company uses access 2003 through citrix. i have written alot of databases in access 97 and need to start converting to 2003. what is the best way to do this. I have my databases split currently. if I try to convert as is, does the back end get converted? will only 2003 users then get to use the database

also my security is controlled by forms. I currently have this control listed on the main form that opens when the DB is started. current user=environ\$("username") then I use an if statement on "current" of the form to display what controls are enabled for each user. I use 2003 to open the database and it converts fine with a few warning messages coming up. the current user control works fine. but then I open it again and it displays an error message and a #name is displayed in this control. I cant figure out why. am I not converting it properly. any help would be appreciated.
