You give a lot of information there, but you haven't answered my question! Can you identify the line of code it's failing on?

Not quite sure what your "compiled the code in Access 2003, so there is no missing references." is implying: you do realize, I hope, that just because the references are fine for a given database on machine A doesn't mean they'll be fine on machine B.

It was my understanding that the Package and Deployment wizard would analyze those dependencies and include them with the installation? Calendar Control for example. Is that not the case anymore with VS2005 tools?

It wasn't really the case with any version. Yes, if the required DLL or OCX was missing, it should provide it. However, if it already exists but isn't the same version, there can be problems. As well, your users can certainly install other software after installing your application, which can cause your application to break.

As to my suggestion as to identifying the line of code that's failing, if your error trapping isn't giving you details of where in the code you are, you might have to provide a customized version of the application that does indicate line number.
