Thanks for the link, however I am not sure how to use the information there for what I need to do?? It talks about named ranges, but the workbook that I want to copy to will be a new workbook each time I export and so will not have named ranges. Also, the sheets that I want named in the workbook, copied from the [JOB REF] field are likely to be dynamic too.

Hi,

I have a query called "CVR Movement", this contains various transactions against various [JOB REF] codes. I want to export the data to Excel and would like the data put into different tabs on the file which is retrieved from the [JOB REF] field. Can this be done in code? If so, where does this need to go? I have Office 2000 if it makes a difference at all.

Thanks
