Hello All,

I am having some difficulty with a series of update queries I am trying to run. Firstly I have a series of "sites" in one table. This is then related to a table which has a number of "scenarios" for each of the sites (and then values which relate to each scenario at each site).

e.g.

site 1, scenario 1

site 1, scenario 2

site 2, scenario 1 etc....

I am trying to create an input form for the site data which will then append the fixed set of scenarios to the scenarios table based on the site id entered into the form.

The problem I am having is that the new record is not being created in the site table before the update query is run and therefore there is no SiteId in the site table for the appended rows to relate to.

Im using a "confirm" button on my input form (which is opened in add data mode) to run the queries. The idea is that the user enters the data and then hits the confirm button. This then updates the the related table.

At what point does the record actually get created in the table? Can I force this? Seems to me that once this is done I can run my append queries without getting a key violation.

Many thanks

Phil
