Since you'all could do it, i decided to try it in a new database outside of my application, and I was also successful. After much consternation, I noticed that the controls in my application had names which contain the pipe character |, while my test case didn't. I changed how the controls were named and presto, success, with one quirk.

There may be a way to work around that, but the pipe characters were definitely not a good idea.

At the end of the sub in which I add the controls and event procedures, I close the form on which the controls exist (it is not the active form) with

```
DoCmd.Close acForm, frm.Name, acSaveYes
```

I thought it would save the form without a prompt, but when this line runs, I am still prompted to save. Any ideas?

I tried this, and found that I was not prompted to save, *provided* that this form was the only object that needed saving.
