I have been struggling with a problem and would appreciate some perspective.

First the problem: I have been creating an application which relies on allowing users to select and sort records using the standard toolbar in a continuous form and then being able to print those records in the displayed order. When successful, this uses the filter name in the OpenReport line and includes an OrderBy statement on open in the Report. This works fine in parts of the application, but in another location, Access asks for a value of the specified sort field and then ignores the Orderby statement.

The only difference I can identify is that the form in the successful piece is based on a table while the unsuccessful one is based on a query linked to multiple tables.

I have compared the working and nonworking pieces of code and can see no difference. I have tried developing the report again from scratch with the same result.

Can anyone suggest 1) things to look at for this specific problem and/or 2) general assistance in how one approaches troubleshooting. (I'd shoot the code, but it wouldn't help!)

Thanks, Lloyd

.
