Hi Ron,

Well it is definately doing something. But it moves it to the ID in the list that relates the previous record.

I did the following to test it:

Created a text box called txtBillHdn bound to the Bill field (the list box contains a list of Bill numbers). Created a button called btnTstLst. On the click event of btnTstLst I inserted your code:

```
Private Sub btnTstLst_Click()
```

```
lstBill_List.Value = txtBillHdn  
lstBill_List.Selected(lstBill_List.ListIndex) = True
```

'Basically two steps. First set the value of the list box to the newly 'created record ID and then make that row the selected item in the list.

```
End Sub
```

Then I went back to the form and used the navigator to go to record 4 with a Bill value of 44444444. Textbox txtBillHdn is now 44444444. So I click on btnTstLst and it selects 33333333 from the list, the Bill value for record 3. Any idea why that might be happening? Definately on the right track though, the list selection is moving up and down.

TIA,

Jarryd
