Hi All,

I was wondering how do i create a form type dialog with several option, and depending on the options that are selected it filters out the results,

Ive created a query, relating to me project table,

i have created a unbound form, and added all the required fields which are combo's extra and the linked all the associated fields under the criteria field on the query back to the dialog form i've created.

the dialog search form works fine, only if something is selected on each field.

What I'm actually asking is that if the a particular wanted to ignore say the Quoted Combo and left it blank the query would display both Quoted and Non Quoted projects, depending on what the other criteria was used of course!

does that make sense?

What you need to do (and it sounds like you may already be doing it) is to parse a SQL string based on the current settings of several on-screen controls. Presumably, the trigger is the change event for each control. If some of these controls are textboxes which may be blank, then you want to test for NULL, and parse the SQL command accordingly.

I have found it useful to divide up the SQL string into substrings each represented by a global variable with module scope and then assemble them into the final string at the end.
