Hi Bruce

Yes, you should Dim dbBE as DAO.Database. (It could be declared as Object, but every database should have a reference to DAO anyway, so early binding is faster and gives better compile-time checking.) In any case, it will need to be declared.

BTW, EVERY variable you use should be declared. using implicit declaration is asking for trouble. EVERY module, including Form and Report modules should have Option Explicit at the top.

The path to the backend is just that – the full file path – for example:
"\\MyServer\SomeShare\My App Folder\Back-end file.mdb"

BTW, there is no law that says an Access database must have the extension "MDB". All my backends are .ABE files (Access Back-End). It at least discourages users from double-clicking on them to open them!

I'll give that a try when I have a chance to get back to it, which may not be tomorrow. Two more questions for now: Is there any need to made the dbBE variable a DAO.Database? And is the path to the back end a path first to the Access executable, followed by a switch that includes the path to the BE (like with decompile, etc.), or is it just a direct path to the BE file?

BTW, I don't think I have a project so far with more than maybe 20 tables in a single BE database.
