When you have a parameter in a query, SET the .PARAMETER object variable before opening the RecordSet.

David wrote:

This is SO frustrating, as I did this ages ago, but have since lost the code and I've been trawling the internet all day.

All I want to do is pass an argument to a select query. The field name is 'Authority Type', in table 'Authority'. I'm positive there was a docmd function or something similar. I tried using .parameter(), but don't quite get how that works. I stuck some dummy criteria in the query, but the parameter.count value never showed more than 0. Is a parameter something else entirely? RETARDED.

Is there not something like qdf.execute(Where options) or something???? I just need to pass the field name and lookup value!!!

```
Dim stDocName As String
Dim db As Database
Dim rs As DAO.Recordset
Dim qdf As QueryDef
```

```
Set db = CurrentDb
Set qdf = db.QueryDefs("Authorities") 'Authorities is a basic
two-field query
Set rs = qdf.OpenRecordset
Do While rs.EOF = False
thisAuthority = rs(1).Value
MsgBox thisAuthority
rs.MoveNext
Loop
```
