Without knowing the entire sequence of your operation, I can suggest that you use ME.Undo on the form to undo all the changes that you have made.

That assumes that you are opening a form to a specific record and then using the values of the form's controls to build your Insert query.

Alternative would be to create a new record that is a duplicate of the existing record and then modify the duplicate. That would mean you would not need the insert query and you would not need to worry about modifications to the existing record. You would need to handle the situation where the record was duplicated and then the user decided to make no changes.

Hi folks,

I have a need to edit existing records, using a form, and save them as new records (to keep a running history of changes). I created an INSERT query to add the edited records as new ones. That works fine. However, the record I'm using to populate the form is also being changed. So... in essence, I'm always creating a new record that's an exact duplicate of another, **ARRGHHH!**  
I just want to create the new record from the source data and leave the

Re: Wierd behavior while inserting a record...

original record alone. Suggestions anyone?!

Thanks,

TC2
