Hi

I have a client that is entirely wireless except for the server machine which is hardwired. I've read up on why you shouldn't use wireless with replication and I've also read the posts about the USB drive as well. I'm trying to figure out a hardware solution (even though I've always been the software person.)

I want to replicate the database on to a wireless laptop and have them load the data to the server somehow via the server machine. I know that copying the database from the laptop to the server machine is not feasible. Can someone suggest a way to tie the laptop and the 1 hardwired machine together (albeit temporarily on a daily basis) so that the synchronization can take place?

Thanks

Jeff
