I've encountered a most interesting anomaly in A2003 Reports. I have a report containing two columns. The Detail_Format event is triggered twice at the beginning of each column. And, since I'm doing some calculations on each record being formatted, my calculation totals are incorrect by exactly the amount reflected in the records corresponding to those that fall at the top of each column. Needless to say, it took a bit of debugging to finally trace the source of the problem.

Is there some explanation as to why the event "fires" twice when a new column begins?

I can keep track of RecordID's to detect when this is happening, but I suspect there's a better way to know what's happening?

Thanks,
Bill

Formatting events in reports fire multiple times for lots of reasons. Some times many more times than just twice. You cannot use these event to reliably perform calculations.

Usually controls with their RunningSum property enableed can be used to perform such calculations and they don't have the same problems.
