Alright, I should make a profile eheheh

SBS 2000, running ISA, two nics (similar setup to the smallbiz.net two nick with isa setup) we connect to internet via external nic through router to cable modem. Currently I am using each client in my domain to attach to one mail account at our ISP to send mail. Each client Pop3s to another mail server to get mail, receiving mail has not been a problem. sending is.

ipconfig/all from server .. not really. Internal is a 10.0.0.x
external is 192.168.1.x, everything is running fine, or so it seems.

HOWEVER, what I gather, is that when two individual workstations log into this email account at the isp to send mail, some sort of collision occurs, THEN outlook tries to send via exchange. and it fails because the current exchange setup does not work.

does that help ??I need some help configuring exchange to send via the one email address at our ISP. They are VERY little help, basically hiding behind the, "we dont offer support for our clients networks".
