Once the machine is joined to the domain, you need only to have created the domain user account on the SBS. Domain user accounts are then automatically members of the local Users group on the workstation.

As your needs require, add that domain user to local groups on the workstation (such as Administrators, IF it is necessary for the user to install things). I would avoid that as much as possible and use other means to manage software etc. on the workstation (install as Administrator, use Group Policy software installation etc.)

Since you have ISA, the domain user account (or domain group it is a member of as appropriate) will need to be added to the BackOffice Internet Users group on the server to have internet access, in most cases. A local user account will not have access through ISA unless you have some type of allow-all rule configure in ISA.

If you choose to make that user a local Administrator, they had better be a very cautious internet user, and you should have very good security mechanisms in place (anti-virus/spyware etc).

How you choose to handle it should be whatever makes the most sense for your situation. The users at my company are fairly unskilled with managing PCs, so I do all the config and keep everything fairly locked down.

So there is more to the procedure than that outlined in KB316418

It would be correct to have to create a user member of MYDOMAIN with admin priviledges on the workstation?

Regards

Users must be a local admin on their workstation for workstation to run scripts/install software.
