I am extremely new to using HTTP, so feel free to answer me as if you're talking to a 10 year old. I have to send an XML file to a vendor via HTTP. I have a send port with a transport type of HTTP, and I have the URI set to what the vendor gave me.

Here is what is supposed to happen. I send them the XML, and they immediately send back a response to say if the XML is valid.

Then if the XML was valid, I receive (maybe in 4 hours or 4 days) XML via HTTP that will be an order rejection (maybe they no longer stock an item or something), or ship advice XML (the order has been shipped and processed successfully).

Now, I think I understand how to set up the HTTP receive for when they send me the order rejection, or ship advice (I will use correlation and set up the receive ports, etc... for this part, I have to provide my vendor a URL).

What I don't understand is how to view/interrogate the XML that they immediately send back when I first send the order. I've looked thru the SDK and examples, and from what I can see, I don't need a receive port for this part, and I don't need to provide the vendor a URL... somehow I can just view/interrogate the response I get back...but how????

Thanks in advance!

Brian
