Ok, if you are getting one as a value back, something is really really weird if no update is made Here's the only thing I can think of. Make a Totally unique record, something with a very distinct value in the column in the where clause. Then send it through....Verify the Parameter Values beforehand. If those values are correct and the where clause value is legit, there's no reason it shouldn't work. I know this is silly, but verify the database you are writing to as well in the connection string, make sure you aren't pointing to test and looking at production or some such. I just mention this b/c this is very weird and it's getting weirder. Sending an update command is standard far and there's no reason that it shouldn't work.

Also, did you run the Select statement beforehand? I'm wondering if it's returning one record like it should be if the where clauses match. And there's definitely no exceptions beign thrown anywhere right? I'm assuming that b/c of the records affected but we need to check every avenue.

Don't get discouraged, we'll get it.

Bill
