Hi all.

When I first heard about VB.NET it should be so easy to update "Mother/child" tables. Just build at datasett with all the tables, do the changes and run .Update.

Well, I cant get this to work that easy. Do anyone have some pointers on how to do this.

Pseudo example.

I want to insert a new Customer. The customer is connected to a Statistics, Postalcode, FreightDeal, Contacts, ExtendedCustomerInfo..+++++

I just want to load a "blank" form and insert the values an push OK. Then ..NET inserts all the values where it belongs. When working with the customer an button opens e.g a contactform for new contacts and so on. All without saving anything to the database yet. All tables have identity and one to many relations. One customer can have many freghtDeals and so on.

In VB6 we had to first save the customer, get the identity an save tables. So, if we wanted to add FreightDeals when we inserted the customer we first had to save the customer and then insert one and one FreightDeal. And offcause the user canceled it all at the end and we had to delete all the records.

I am sure this is elementary, but can't seem to get the hold of it. Any pointers to help on this are welcome.

Thanks all.
