The other problem I have which this does not address is that I am only updating one table in the database, but am displaying data from 2. So I need to choose a value in the combo box, then update the hidden field with the correct id to write to the database while showing the correct user-friendly value. I used to do this in VB6 all the time, but I am trying to do this "the .NET way" I am wondering if I just need to write all the plumbing code that I had to before. I was hoping there was a way that ADO.NET handled this kind of situation.

.
