Then it will residet on the client machine. The application will be loaded into the memory of that machine, and so will any variables/data that this application uses.

To run it on the remote machine, you would have to log in through terminal services, and then run it.

Think about it, when you run an install off of a network share – the program still gets installed onto your machine, right? That's because the program gets copied to your machine and loaded into memory, and then it runs and installs onto your machine and not on the network share. Same here.
