Well, first I would ask "Are the website (I'm assuming that's what you mean by Extranet) and Intranet going to be on the same network?". If they are, all you need to do is set the appropriate permissions for the directories you want on the Intranet, Extranet, and neither. If they are not on the same network, I would probably go with Web Services. ASP.NET Web Services use XML to transfer the information. You may also want to ask some of the other newsgroups that are more about IIS and networking, because there may be other ways as well. Good Luck!

Hi,

I have the scenario where I have one database and need to allow to see the information accessible from Intranet and (future)Extranet. I wonder what is the most feasible and secure way of doing it without buying second license for MS SQL and duplicating data. So far I am leaning towards Web Services but we have ideas for MySQL, XML and using FTP to transfer the data in files. Which way is the most secure and feasible or is there something else.

Any help is greatly appreciated,  
Tom
