Hello!

I'm a bit confused... if you're using Windows authentication, why do you need to "validate the user against a list"? IIS will validate the users for you.

interanet. I have been able to take the advantage of Windows Authentication,
but the idea of having a hardcoded list of users creates a lot work and
almost become inpratical. Therefore, it would be so much help if I can
validate the user against a list in a database that I can maintain through
the actual application?
