you should try ASP.NET Caching, excellent utility to speed up web page.
it can cache your control and data. It reduce the frequency to read from database for less volatile data.

threading not good for asp.net

:)
heehee

I have a question regarding the way that we can load page components separately, so that a user sees various parts of a site load as the data comes back, but the whole site in general is already loaded up, so it looks like stuff isnt being held up and it looks more realtime.

this happens on something like project server, as the page loads up, it doesnt hang waiting for stuff from the database, it just fills parts in as they come back. i know a little about threading, is threading the ultimate way of doing this or are services etc good ways of thinking about this.
