Hello,

I was wondering what the best way would be to dynamically determine and store connection string information. What I mean by this is that I want the application to use the servervariable to determine what location it is running in and then dynamically assign a connection string value based on that location. I was planning on doing this from the codebehind pages which works fine because I am able to use the response object to determine where the code is running but I am not sure what to do in a vb class file where I have no access to server variables. Any Ideas???

THANKS
