Hi Param,

As Karl has mentioned, ASP.NET 1.x and 2.0 can be deployed on the same server side by side.... On server box with IIS6, we can configure different application to running in different application pool , and even creating multiple websites (if server version OS) and configure asp.net applications of different versions hosted in different IIS site....

Also, hosting asp.net 1.x and 2.0 apps in separate sites are better to manage since sometimes they'll conflict ... e.g when a parent web application (maybe site root) is configured as ASP.NET 2.0 and has a web.config (with some 2.0 specific configure elements...), if there is another sub asp.net 1.x web application deployed under that 2.0 app's sub application virtual directory, it will throw parse error when starting since sub asp.net app's web.config will inherits config info from parent virtual dir(or site root)'s web.config file.... Thus, asp.net 1.x app can not parse 2.0 specific configure elements(like connectionstrings....)

| They can both run side by side. I believe in IIS 6.0, you can configure this

| per application in the new ASP.NET tab you'll see when you go into properties of an application in IIS. On IIS 5.0, I think you need to switch

| back and forth between the two.
