If you want a single location for configuration data, consider the database. But then of course you have a bootstrapping problem of how to tell each server what database to connect to. At some point, each server needs to be informed where to go look for your configuration data.

Hi,
I'm building an application that will probably sit on some load balanced servers at some point and I'm concerned about keeping configuration settings in the web.config file. Is there a tried and tested method of holding config information in static classes or in the cache that someone could point me to?

Cheers,
Tim.
