Hi,

Maybe there is another way of doing this, but here's my problem...

I have my web site where I have a master page to have a common layout and a common behavior on all my pages (that's what it's intended for)... But now here comes the time where some pages need some processing (like, is the user logged? and those kind of things)... If it was only on 1 or 2 pages, I'd say, i'll put it directly in the code and case closed, but there are 10-20 pages that need this behavior while 10-15 pages don't... So I'd inherit my master page to include everything in the base masterpage into the new master page that will do the additionnal processing... and use this inherited master page in the pages that need the extra processing... Can it be done?

I've thought of another way... that would be to create some properties in the master page code file and setting them in my "sub-pages" to know which processing to use... I can set these properties fine in my "sub-pages" code, but is it possible to set a Master Page's property right in the markup like we do for user controls?

thanks a lot

ThunderMusic
