websites run in their own appdomain so they can nt share variables. you need to use a common shared resoure, file, databases, com+ service, webservice, remoting, ... that stores the values.

Hello my name is Craig.

I am wondering if it is possible to have 2 websites that are based on the same web server and if somebody enters some information into a textbox on 1 page and then clicks the button to send that information. Is it possible to have that information that was sent to appear on the second page if the other user refreshes that page.

This isn't like a response redirect or session type variable thing. I realise that this could probably be done using a database but I was wondering if there was another way of doing this by storing the information on the web server like a global variable of some kind.

Thanks for your help.
