If you use the VS tools to help set up login, it will place the config element for you. It will also watch page name changes and adjust config accordingly. You can "trick" it and mess things up, if you try really hard. Fortunately, it is a simple matter of manually configuring through the config file. ;-)

In VS2005, I create a ASP.NET website project. One page named Default.aspx with LoginView and LoginStatus controls; and one page named Login.aspx with Login control in it. After setup of users, I press Ctrl+F5, IE window is popped up, redirect to Login.aspx page ask me to input username and password. This works fine.

I am wondering, how does ASP.NET know to redirect to Login.aspx from Default.aspx? I renamed Login.aspx to something else, and it still works fine.

I add another page named AnotherLogin.aspx with Login Control too. But, Default.aspx doesn't redirect to AnotherLogin.aspx, but to original Login.aspx. What's the connection between Default.aspx and Login.aspx? How to configure it?

Thanks
