Hi,

Well, to place some annotation in runtime inside a Web-Browser it will require lots, and lots of code (preferably) in javascript. Specially if you're wiling to serve different platforms (i.e. Browsers)

Only browser scripts can respond to mouse events, and event so the code needs to be short for there would be a huge impact on performarce if the code in mouse events are too long.

You need to realize that the browser environment is very, very different than desktop app.

You don't have any control whatsoever on what it will be displayed on the user's box.

Yes, you can do wonders with javascript and css, but the user can override every single item and then your beautiful app may crash soundly.

Developing for web, specially targeting different platforms, is very tricky.

Regards,

Paulo Santos

After serious thinking chandan wrote :

Hi,  
Is any way to palce a control(button/label) at a location on  
webPage  
in runtime??

In page\_load envet I am adding a button on the page in the  
contol  
collection of a panel but not able to specify the location of  
the  
button since button controls did not have location property in  
web.

I am trying to place a control at mouse click position on the  
page.also I am not getting the mouse down position on the  
page I am  
working on that.Actually I am windows Programmer and all  
those things  
are done in windows very smoothly.

Let me know if any solution!!

Cheers,  
Chandan Kumar

Web applications are very different from windows apps (as you found  
out).

There is no direct interaction between the codebehind and the form, as  
they are living on different machines: codebehind runs on the server  
and the form "runs" on the client's browser.

Control alternates between the two: when the server is done, it spits  
out HTML text. This is received by the browser and rendered into a  
screen. When the user clicks a button, an HTTP request (or "POST") is  
sent back to the server. The browser then waits until the server sends  
a new HTML response.

Re: Is any way to palce a control(button/label) at a location on webPage in runtime??

You will never get the server to react to mouse–events in the browser:  
the delay would be too much.

With additional coding in javascript and the use of Ajax technologies  
you could get a somewhat smoother response, but not the same as in a  
windows application.

Thanks Hans for giving this knowledge. Actually I think this problem  
in windows mode.Now suppose I have a panel on the page and then can I  
palce some control on panel at runtime as I think there is click  
envetn on panel.I am trying to do this if you have some clue then send  
me.

Actually I am workig on a charting application and I have to place  
annotation on the chart at run time.

Thanks,
