Hi,

I'm currently expanding the capability of an Access 2000 database for a customer who's limited by the "regime" of it's IT-department.

The client wishes to do things in his Access 2000 (with VBA) that are easily done in (vb).NET.

I have finished an ActiveX component that works well when tested in a VB.NET 2003 environment using 1.1 framework (client has 1.1 installed).

I've got register class and unregister class (inproserver32 etc.) and when compiled, on the same machine it works wonderfully well in Access 2003. However, the customer uses Access 2000 and Windows 2000.

So I've created a virtual machine running Windows 2000 with Access 2000.

My question now is (application has strong name) how would I implement this the right way. I've used Regasm and I've checked "register for COM interop". I've placed the .dll and .tlb in the same folder as MSACCESS.EXE and still I'm experiencing difficulties. Like Access mentioning it's not registered properly, or when it finally works the next time you enter the form it's says something about the ActiveX component containing no control.

I registered the dll like this:

```
[path to]\regasm /codebase myactivex.dll
```

And also without /codebase.

Do I need more ? Do I need to go about this from a different angle ?
Please advice !

Kind regards,

Martin.
