We had a strange thing occur that I cannot duplicate and therefore debug and fix for next time.

This is an app and web service that have been working together with WSE2 for many many months. Last night I was told that on one particular function in teh application, they were getting the above message. Over and over again from numerous computers. This morning, when I tested it from MY computer , hitting the same webserver, I did not have the problem. They said the problem also disappeared this morning.

I don't know where to start investigating this. This function was the 3rd in a series of WSE2 wired web services calls. So it wasn't that the webserver disappeared. They would always get past the first two and then get this on the third call (the particular function).

What type of event would cause this to disappear and then reappear. These computers were all hitting the webserver through the internet and through an ISA Server. They endpoints have not changed. Nobody edited the policy config file.

Can anybody get me pointed in the right direction?

Thanks!!

Julie Lerman
