Hi, all

I've got a windows service (server) application and a winforms (client) application. What I need to do is to host a web service in the windows service application so the client can request information about its current state and request server's internal data to change on user's behalf, plus I need to do it in a standard compliant way, such as xml/web services.

Any help/link/info would be very appreciated
Thanks

.
