Hi,

one newbie general question:

I just started to write a vb.net webservice that is consumed by a .net application (client). Now, as there may be lots of clients for one web service when I release the application, each client has to be configured to use the correct url to the webservice. Now, this can be done by setting the .url property like this:

```
.url = "http://www.anyserver.com/test.asmx"
```

The url string has to end with *.asmx to point to the actual asmx- file. But, when I take a look at my test.asmx I can see something like this:

```
<%@ WebService Language="vb" Codebehind="test.asmx.vb" Class="test.Service1" %>
```

Here comes my question: The codebehind statement indicates that I'll need to ship the *.vb file with my source code to let this work – but I just wanted to ship the compiled dll and not my source code. How do I have to set the statement above so that it makes use of the compiled dll and does not need any *.vb files?

thanks a lot
Peter
