Hi,

There are several ways:

1)if you are using IIS5.1 you can change the user that is impersonate on the webservice, you can go to the machine.config file and remove the default ASPNET user, this has some implications related to security, because it will change the default user for all your sites on the server. (This is not the account that the client will use, that is a different layer and will still use IUSR_MachineName). If you want to do it per website you can paste that code on your web.config file (note: I haven't tried this, I know that some properties can be set on the web.config but others are ignored and read it from machine.config, check the help for this)

2)If you are using IIS6 you can easily change that on the website properties, so its per website, same behaviour as above.

3)If you are going to impersonate remember that only works on Wind2K3 and XP, for Win2K you need to change the policy settings in order to do this opening a whole on the security environment.

I prefer the option 1 cause I have more control, but check your requirements and choose your best approach.

Best regards
Salva
