I have a form with several textboxes, checkboxes and datetime boxes on it. I am databinding all these controls to a typed dataset.

I need to be able to add new record, and navigate the records with next, prev, first and last buttons.

i am adding new record using `bindingcontext('dataset.table').addnew` (i am fixed the problem with the checkbox's). This works fine, i get the next record added.

i am moving to the next record by using `bindingcontext('dataset.table').position += 1`

i am moving to the previous record by using `bindingcontext('dataset.table').position -= 1`

I call `endcurrentedit` before each position change.

Here is my problem, if i load my dataset with data on initial load, i can move backwards, forwards as much as i like and everything works great. If i add a new record, the record is added and the position is set to the new record. Now if i hit the previous button it moves backwards one record no problem, but then if i hit next button it does nothing, but if i hit the next button again it moves to my new record.

It will move backwards as much as i want, the problem occurs when it moves from the original records to the first new record. To move from last original to first new you must hit the next button twice. But you can move forward through as many original or if you have multiple new rows you can move through these rows no problem, it is just that move from last original to first new that requires 2 clicks on the next button

Thank you
Mike
