There is too little information in your question for us to help you debug your problem, friend.

Please provide a short but complete example of code and a description of how to recreate the problem.

You can create an install project fairly easily. In your solution, add a project of type "setup" project.

As for the connection string: with web apps, they are normally installed by administrators, and not by average users. You can expect these folks to be able to edit a config file. So, put your connection string into your web.config file and then reference it in your code. Test this and make it work in the development environment. When you deploy to test, send along instructions on how to edit the config file to change the name of the server and/or database. For best results, use integrated security to access the database.

Hope this helps,  
--- Nick
