Can't suss this out for the life of me, googling of no help either.

Okay, new to win forms; I have a treeview with several root nodes, each having a single level of child nodes underneath. I also have a context (popup) menu which, what I want, is for it to pop up with certain options (menuItems) when a root treeNode is selected and different options when a child node is selected. It is all working well except for one problem – if I right click on a childNode I still get the context menu options for the parent (vica versa too)

This happening because the right click on said child node does not cause it to be selected, the parent node remains the selected node! But I do not want people to have to first left click to select the child node and then do the right click to bring up the context menu with the appropriate options – most apps I see don't force this as a requirement.

Assuming I explained that all well enough, anybody got any ideas on what I need to be doing??

TIA.

Andy.
