I want to create a Word document that will display data from a database. I don't want to create the file on the server, I just want to stream it out directly to the user. When they click a button, the Word Save Open window will open, and allow the user to Save or Open the document in Word. I know I need to use `response.binarywrite`, but I don't know if it is possible to create the binary object without first saving it to a temporary file. Would I need to create a Word template, and how would I use it?

How would I get data from a data grid into this document?

.
