I'm not sure if this is the right group for this posting. If not, please accept my apologies.

I have been tasked with identifying and correcting application code that will be affected by the new daylight saving time change that goes into effect 2007/03/11. This is a .Net application with thousands of lines of c#, javascript and html.

As I currently understand it, relevant patches will be supplied and applied to the affected web servers so the time will be reflected correctly at the OS level.

Beyond searching for daylight saving time-related methods/functions and literals like 'daylight' or 'saving' or 'time', etc., I'm at a loss as to how else to identify potential application problems.

I've googled and have not found much of value in this regard yet. Does anyone have any thoughts on how best to approach this?

TIA

.
