Have you checked the event log to make sure something in the redirect isn't causing the site to crash and therefore restart the ASP.NET worker process / site?

I realize that. But this is starting a new session in the same window. It should start a new session with the window.open, but not on a redirect to another page within the project. And whats worse is, its random. Mostly starts a new session, but about 20% its just fine.

All the sudden my app has started to loose Session values after a Response.Redirect to another page in the same project. Ive

Re: Losing Session vars on Redirect – HELP

read several
post
about setting the Terminate Boolean to false to solve this
problem, but
it
hasnt work. On top of that it seems total random.

I have a start.aspx page that all other web application call to
begin
the
process. This start page creates needed Sessions and other
miscellaneous
tasks, and then redirects to another page that uses the session
data.

This only seems to be affecting me when Im using a model
window to
redirect.
Now I know model windows open a new window when
something in them
causes a
post back (and we figure a way to solve that problem long
ago), but
this
is
happening before the page is rendered.

Placing breakpoints in the code shows that
Response.Redirect is firing
off
Session_Start in the global asax. Overriding the browsers
cookie
handling
to
allow session cookies works, but it also configured as
cookieless=false
in
the web.config for the sessionState, so even if I didn't
override the
browser
cookie handling, why is it working sporadically (very
sporadically
actually)

Any ideas. Im using C# and VS2005?
