You mean connection with your server in SMTP protocol, or connection with
the Internet?

Most probably it is connection with the Internet that is not established at
the moment of error. Address smtp.xxxxx.yy must be translated to IP with
help of DNS server, if DNS is not available then name query will rise an
error mentioned before. I suggest you to simply catch this exception and
inform user about it in more understandable way. You may also think about
trying to establish a connection, but that is a different issue.
