Hello!

I have one solution file that consist of three project.

One project that build the exe file.

One project that build a class library dll

One project that build a windows control dll

In the windows control c-tor is there a call to a method in the class library.

So in the project referense settings for the windows control I have a project referens to the class library.

In the exe file c-tor I have a call to a method in the class library.

So in the project reference settings for the exe file I have a project reference to the class library and to

the windows control because I can drag the windows control from the toolbox to a form in the project that build the exe file.

Now to my problem if I now rebuild the project only for the class library and then try to drag the windows control to a form I get the following error "An exception occured while trying to create an instance of Middle.Middle. The execution was "?"."

But if I rebuild the windows control instead then I can drag the windows control from the toolbox to a form in the project that build the exe file.

My first question why do I get this error.

My second question is what is the recommended setting for copy local that exist on each project. It it to have true or false.

My third question is what requirement is it about the version that each dll have. I mean when an exe file will call a dll or when a dll will call another dll.

//Tony

I just wonder what is the requirement about the dll and its version on the

Have big problem with windows control dll

dll

I noticed that when I get error

.
