I'm looking for an event that will fire once a tcp port moves from the listening status to established status.

You should probably learn more about TCP first.

There's no such thing as a TCP port moving "from listening status to established status". An entirely new connection, with the "established" status, is created when an application with a "listening" TCP port accepts the connection. But the "listening" TCP port remains, and is still listening for new connections.

I want this to run as a service so I don't want it to chew up cycles constantly checking for a specific port to move from listening to established that's why I ask for an event.

Short of sniffing the network traffic and watching for TCP connections being created, I'm not aware of any way to do what you want. Not directly anyway.

One thing you could do is poll the TCP status and check for new "established" connections on the same port as a "listening" port. Obviously you wouldn't want to poll too often (maybe once every 5 or 10 seconds), but this would be one way to do it.

The obvious problem with this is that a connection could be closed and then reopened between the time you've polled, or opened and closed for that matter. You won't get guaranteed notification of network connection changes this way, but it might be close enough for your purposes. Depends

Re: Check for activity on TCP port

on what you're actually doing.

Basically I want to execute some code once the port moves from listening to established, and then run some clean up code once it moves from established back to listening.

If you think it might be useful for getting better advice, you might consider being more specific about the "clean up code". I'm having a hard time imagining what one process would be able to usefully "clean up" in response to some other process connecting or disconnecting TCP connections. There's a small possibility that there's an entirely different approach to accomplish what you're trying to do, but no one can offer that information if they don't know what the end goal here is.

Pete

Pete,

Thanks for your insight. Basically I'm using VNC for remote administration. Vista's new aero glass slows down the screen refresh rate. Basically I want to watch for the VNC connection, when it's detected, disable the aero experience, and when the connection is closed, turn aero back on.

I think your explanation will work out just fine.
