hi ,

Does a singleton statusbas controller sound correct. I mean , is that how its done?

IT does not sounds correct, as a matter of fact it DOES sound incorrect. The statusbar is just another control in a form, you should let the form control it.

I have a big app and i need to control the statusbar from within a number of custom controls , dynamic menus and toolbars etc. So should i have the aforementioend class? I'm thinking singleton so its instance is globally accesssible?

you better define an interface (that your forms can implement) in such a way that it return the instance of the correct statusbar. Then you can just call a method (defined in the interface) to make the update.
