Hi all,

I ran into a headache problem. I have a windows form with a progress bar on it. Then I new a thread to do calculation for a long time. I want the progress bar to show the calculation progress. So I use a shared variable in calculation thread to allow main thread read it periodically in order to show the progress. Question comes out. If I just wait and don't make any operation during the whole calculation, the main form is OK, with progress bar increased step by step. But If I click other application or just drag the form, main form will have no response until the calculation finished. At first I think that maybe the calculation is too tight to be a circle. So I add several sleep() in it. But this method is of no use. I have no idea this time. Anybody can help me? Thanks in advance!
