

Buggy Datagridview?

I and another developer have created an app that uses a datagridview to display market information. The datagridview is fed with messages from another app on a server that feeds the messages through msmq to the display app.

The problem is that when writing to the rows values from row x column 2 get stuck in row x column 1. The correct value is displayed in row x column 2 but also shows up in row x column 1. The colors of the two columns are different so it sticks out like a sore thumb to the end user when the value from the column next to it shows up in the column and it is even the same color as the intended column.

We have ruled out that it would be a issue with the way we write to the cells because I can resize the column and the bad/stuck value leaves the incorrect cell.

I also see the gridlines that seperate the columns disapear on a random row occasionally too. The same fix for this problem applies as well. I can resize the column and the line repaints.

As soon as a new value is written to the cell it also cures both of these problems as well.

The speed in which the cells update is quite fast, but it still happens when cell updates are fewer. Its just that you don't see it as often.

Any Ideas? It seems like a .net bug or bug in the datagridview object.
