It does help greatly.

Im new to vb as well, and I am glad I updated to the 2005 ver. Even if it is express. It is way better, and handles some objects better. Plus now when I go search on google, I know everything will work.

Thank you for all your help.

Two last quick questions.

1. In the code – where you define the "Namespace" . Is there a list of "reserved" namespaces or can I choose any word I want for a namespace.
2. I am supposing I should keep the myTrimText.vb file with the property setting on 'Compile' ?

Ive been searching google with "inheritance" but things come up that I'm not really looking for.

Thank you again for all ur help.

yup.

That is what I expected ... Sorry, I am new to VB and VB.Net (just started using it about 6 months ago) and I am not sure what is specific to VS 2005. That is all I have ... never used other versions.

As you can see, the custom class (user control) will appear in your toolbox and from there, you can drag and drop it on to other controls.

As for you next question ... button with picture box ... yes this is a perfect example for using inheritance ...

Re: Handle Worked – can someone please double check

Lets says you have two types of buttons you want to do this (onLever , onEnter, onClick) with ... an OK button and a CANCEL button.

First,

1. Create a base myCommandButton ... inherited from CommandButtons.
2. Create the necessary properties ... icon file or whatever ...
3. Code / Extend the events accordingly ... on enter ... on leave ... on click ...

Create a new class myOKButton ... that inhertis from myCommandButton

1. Set it's custom ICON properties to what you want for OK buttons.
2. Now, when you want to use an OK button ... you are done. Drag it, drop it on to your other controls.
3. You do not need to worry
