David wrote:

The "main" web page is a list of service requests links. My program is loading the main web page and then loading each individual service request link. At various points (seems to be random), when attempting to load a service request page, a runtime error is returned. I've tried slowing the program down and am convinced the time between downloading each page is not the cause of the problem.

When the runtime error is returned, I try downloading the same service request page again after waiting 30 seconds. The runtime error will continue to be returned.

If I open an instance of IE and load the "main" web page, the runtime error is not returned and the program continues. IE can be used to load the "main" web page on the computer running the program or on a different computer, same results.

What confuses me is why I can not use the web browser control (again, I've even tried a separate web browser control) to load the web page and get the same result. It seems to me that when the page is loaded with IE, something additional is happening that does not occur when I am loading with the web browser controls.

Ideas on what that "something additional" could be are what I'm hoping to find (or a solution, of course).

I hope that clarifies things.

There is some potentially vital information missing here. What is the error message?
