If you are not interested in having any remains of your application left on the client after using the application then this needs to be an ASP .NET web application.

If you don't want to require any software on the client, then this needs to be an ASP .NET web application.

If all you are trying to do is send some data to your SQL server, then this needs to be an ASP .NET web application.

It sounds like you simply need a web page that collects data and populates a SQL table.

Questions about creating an .net 'executable' 2005 that will not remained installed once a user enters some data into the application. I also want this application to not require any previous software installed on a users workstation.

I basically want to setup an application for new users when they are applying for insurance. This application would preferably be a run as a windows desktop application versus on the internet. Once the user enters the save or submit button, I want the application to send the data back to be processed on a Sql server 2000 or sql server 2005 database.

I have Visual Studio.net 2005 currently and would like suggestions on how to do steup this type of an application using Visual Basic.net 2005.

Thanks!
